## The economic productivity at the German coast

Charlotte Hagner

*33 pages with 6 figures and 15 tables*

### Abstract

In this report the economic productivity of the German coast is compared to selected inland areas. The analysis is based on administrative district data over the period 1991–2000. As economic indicators the total gross added value in the economy as a whole, per person in employment and the gross added value in four different sectors are chosen. In general town districts and surrounding areas are more productive than rural regions. German coastal towns however have a lower gross added value per person than selected wealthy inland districts. Along the North Sea and the river Elbe from the estuary to Hamburg some of the regions have a much higher economic productivity than those along the Baltic Sea. The lowest productive coastal and inland regions are in the ‘Neue Bundesländer’. In all areas discussed in this report most of the gross added value is generated in the service sector. In general this is also the industry with the highest productivity. However, especially in the coastal towns, the manufacturing sector, or the sub-category the processing industry, has the highest economic effectiveness.

## Die ökonomische Produktivität an der deutschen Küste

### Zusammenfassung

In diesem Bericht wird die ökonomische Produktivität an der deutschen Küste analysiert und mit inländischen Gebieten verglichen. Als Indiktoren werden sowohl die Bruttowertschöpfung auf Kreisebene und pro Erwerbstätiger als auch die Bruttowertschöpfung differenziert in vier verschiedene Wirtschaftssektoren in den Jahren 1991–2000 verwendet. Im allgemeinen ist die Bruttowertschöpfung in Städten und in den angrenzenden Kreisen deutlich höher als in ländlichen Gebieten. Allerdings ist die Produktivität in einigen inländischen Kreisen deutlich höher als in allen betrachteten Küstenstädten. In einigen Regionen an der Nordsee und der Elbe von der Mündung bis nach Hamburg liegt die Bruttowertschöpfung pro Person weit über den Regionen an der Ostsee. Die ökonomisch schwächsten Kreise liegen in den ‚Neuen Bundesländern‘, sowohl an der Ostsee als auch im Inland. In allen Kreisen wird im Dienstleistungsbereich der höchste Anteil der Bruttowertschöpfung erwirtschaftet. Im allgemeinen ist die Produktivität in diesem Wirtschaftsbereich, das heißt die Bruttowertschöpfung pro Erwerbstätiger im Dienstleistungssektor, im Vergleich zu den drei anderen am höchsten. Jedoch ist in den Küstenstädten das produzierende bzw. das verarbeitende Gewerbe produktiver als die anderen Wirtschaftssektoren.

## 1 INTRODUCTION

For a long time conflicts of interests have taken place at the German coast. Economic development and nature conservation are often considered to be mutually exclusive. To get an idea of the economic relevance of the northern German coast, three main questions are discussed in this report:

- how high is the economic productivity in the coastal zones in Germany?
- do the level of economic resources differ between the North Sea and the Baltic Sea?
- are the economic resources in the coastal zones higher or lower compared to other regions in Germany?

In Section 2 it is described what regions are selected for the analyses and how the economic indicators to assess economic prosperity are calculated. In Section 3 the different levels of gross added value are discussed. The paper concludes in Section 4.

## 2 CHOICE OF THE REGIONS AND THE ECONOMIC INDICATORS

Coastal regions in Germany are in the north where it borders the North and Baltic Seas (figure 1). As no data exists to ascertain the coastal economic resources, the coastal zone in this report is defined by administrative rural and urban districts along the shore. Moreover the districts along the River Elbe from the estuary to Hamburg are included in this analysis as we also define this region as a coastal zone (table 1). These coastal rural and urban districts, towns, are compared to selected inland regions and towns. For the comparison of North Sea districts with inland ones the most structurally lagging, rural regions in the ‘Alte Bundesländer’<sup>1</sup> in North Rhine Westphalia, Rheinland-Pfalz, Baden-Württemberg and Bavaria are selected. They can be interpreted as zones having the lowest economic resources. Towns with high economic productivity such as Munich or Cologne describe the upper limit of the analyses. To compare the coastal districts and towns at the Baltic Sea with the German inland structurally backward regions and relatively wealthy towns are selected (light-grey areas in figure 1). Furthermore the inland urban districts are used as a benchmark for the productivity of the coastal towns such as Hamburg or Bremen.

As an indicator for economic performance the gross value added is chosen. The gross value added is a key figure of the national income accounting which characterises the economic productivity of various economic sectors in Germany. In general it is defined as the difference between the gross production value and intermediate input costs in the economic sectors. The gross production value comprises the value of sales of self produced goods and services as well as sales of merchant’s goods. Additionally the change in book value of intermediate and ends products and of self built facilities are added (Sellien/Sellien 1988).

---

<sup>1</sup> ‘Alte Bundesländer’ are the federal states of Germany which belonged to the Federal Republic of Germany before the German unification in October 1990.

The light-grey areas are included in the analysis.

Figure 1: Administrative districts in Germany.

Source: Modified in accordance with Meurer-Landkarten 2002.

In the economic sectors ‘state’ and ‘private, non-profit organizations’ the gross value added is calculated differently. The expenditure accounts are added as income from employment, severance taxes, and depreciations. The calculation method is also modified for financial institutions and insurance companies, because interests and insurance premiums are not interpreted as sales of services (Sellien/Sellien 1988).

Since 1996 the guidelines for calculating the national income accounting have been standardised in Europe. In the European Community Directive No. 2223/1996 it is legally regulated how to calculate regional data of the national income accounting. One of the improvements is the calculation of the gross added value by producer prices. Producer prices differ from market prices by not including goods taxes (value added tax, import surcharge without import sales tax, and other goods taxes such as mineral oil and tobacco taxes) but containing goods subsidies. Due to this approach regional distortions of economic productivity can be avoided. Such problems emerged using the former methods because some economic sectors whose products are highly taxed such as the mineral oil and tobacco industries are regionally concentrated (Fischer/Bergen 2000) (tables 1–3).

The gross added value is specified in different economic sectors so that it is possible to determine their ratio of the economic productivity (tables 4–15). In this report the following sectors are included:

- the manufacturing sector which contains the energy and water supply, mining, the building and processing sector;
- the processing sector, a sub-category of the manufacturing sector, which combines the trade branches of converting and purifying raw materials, for example the iron and metal industries as well as the timber, paper and textile industries;
- the service sector, including the industries of the new economy (with the exception of the production of hardware), the trade, the hotel and restaurant sectors and financial corporations (banking and insurance branches), leasing, public and private services as for example of the public administration or health care and social system;
- agriculture, forestry and fishery (Fischer/Guenther 2002).

To calculate the gross added value of an administrative district or town, different indicators of various data sources are used. In the manufacturing sector the data sets of the cost structure census<sup>2</sup>, the trade report and the investment report of small traders provide the required information. Additionally in the

---

<sup>2</sup> In the cost structure census, data of enterprises with 20 and more employees are collected, as for example turnover, costs, number of employees etc. (Günther 2003).

service sector the gross added value is downscaled by the number of employees or labor payments in the district<sup>3</sup> (Treeck 2002).

For the comparison of the economic productivity of different administrative districts and towns the influence of differing regional sizes has to be eliminated. In this report it is done by dividing the total gross value added by the number of workers, self-employed persons and entrepreneurs in the district (tables 1–3). The gross added value per person in employment is also used to compare the economic effectiveness in the four sectors and its regional variety within the branches (tables 4–15).

### 3 DISCUSSION

In figure 2 the total gross value added of towns and rural districts along the coast of the North Sea and the Baltic Sea are shown. Due to the small regional scale considered here, the economic indicator is calculated in respective producer prices not adjusted to inflation.

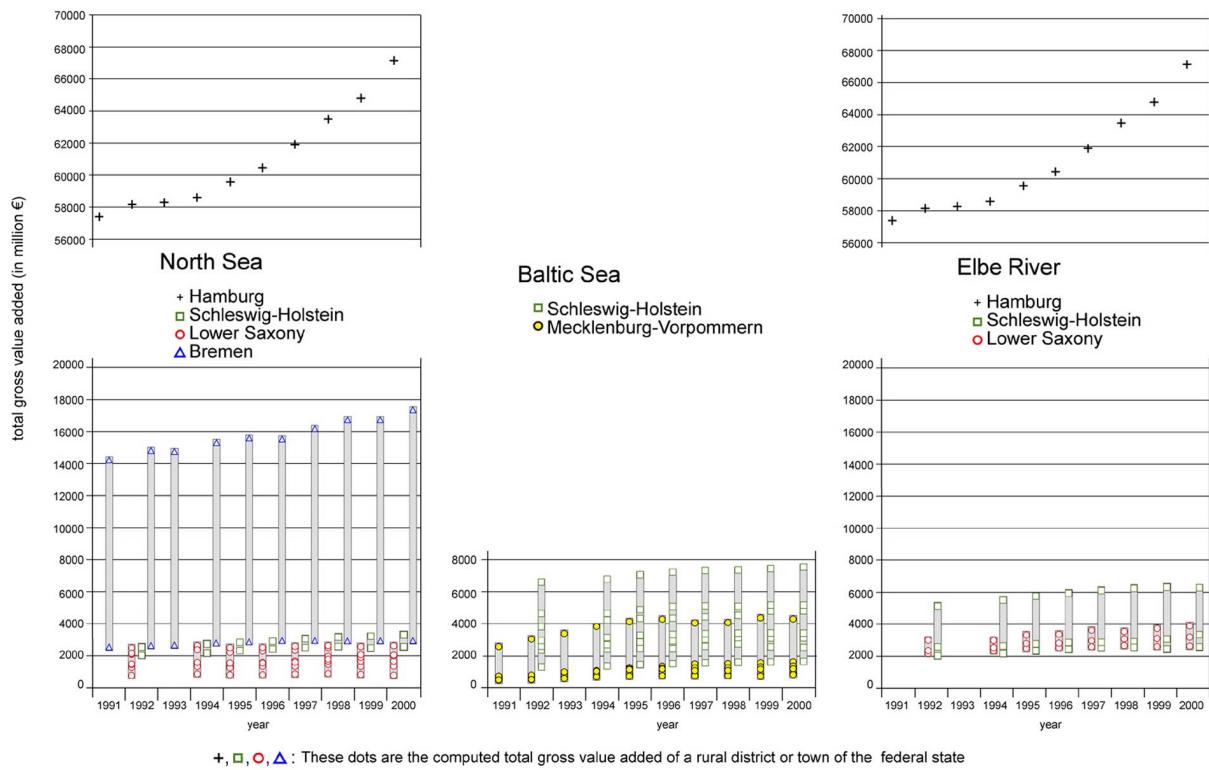

Figure 2: Total gross value added in coastal administrative rural and urban districts.

<sup>3</sup> In the statistics of employees, the number of workers, self-employed and unemployed people are recorded. Furthermore they are subdivided into different categories according to their main way of earning a living, such as for example from pension, employment, unemployment benefit or support from their children (Sellien/Sellien 1988).

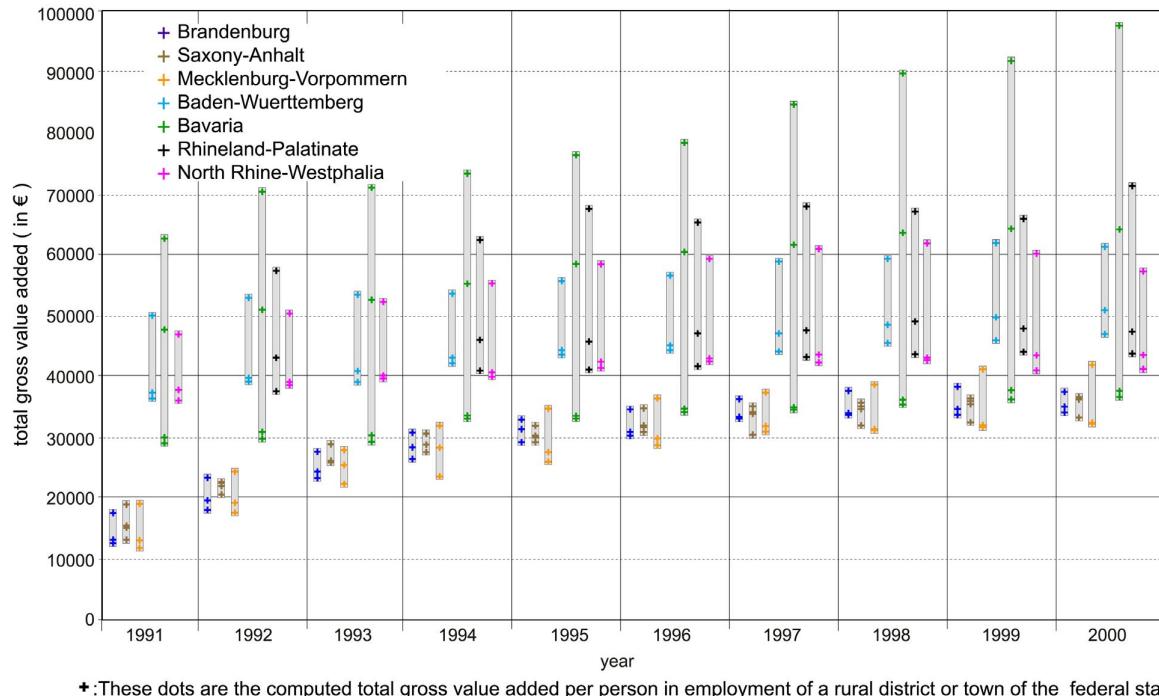

The districts along the River Elbe from the estuary up to Hamburg are also included. It is evident that the level of the total gross value added in Hamburg, which rose from about 57 to 67 billion € over the period 1991–2000, is far beyond those in other districts. In general the three regions differ. This is mainly caused by the towns which are included in the analysis. As for example the high level of total gross value added of 14 to 17 billion € in the city state Bremen is caused by the town Bremen, in Schleswig-Holstein by the town Kiel, and in Mecklenburg-Vorpommern by the harbour town Rostock. If there is not a town in the coastal area of a federal state then the variation of this macroeconomic ratio is much smaller. In rural districts along the River Elbe a higher total gross value added is generated than in regions along the North and Baltic Sea. However in these two areas the lower limit which varies between 800 and 1000 million € does not differ (tables 1–3).

In figure 3 the gross value added per person in employment in selected inland administrative rural and urban (town) districts is shown. This indicator is used to compare the economic effectiveness of high and low productive inland regions to areas along the German coast. In figure 4 the gross value added per person in the coastal regions is subdivided into administrative districts and towns along the North Sea, along the River Elbe from the estuary to Hamburg and along the Baltic Sea.

In general the level is higher in the ‘Alte Bundesländer’ than at the North Sea. But the latter are more economical productive than districts in the ‘Neue Bundesländer’<sup>4</sup> Brandenburg, Saxony-Anhalt and Mecklenburg-Vorpommern (tables 1 and 2). Apart from Lower Saxony the total gross value added per person in employment in towns is conspicuously higher than in rural areas, assigning the upper end of the bars in figure 3 (table 1). Moreover the variation of this indicator is much larger in the ‘Alte Bundesländer’ compared to the ‘Neue Bundesländer’ and the North Sea region. The greatest difference in economic productivity between rural and urban areas is in Bavaria followed by Rhineland-Palatinate. In the suburbs of Munich the highest gross value added per person of all regions discussed in this report is generated. In the year 2000 it was about 98,000 € compared to 38,000 € in the rural Bavarian district Freyung-Grafenau. The main reason for the economic wealth in the suburbs of Munich is the high gross added value per person in the service sector (table 4). Within the service sector the insurance branch and the new technology firms such as information technology and biotechnology are of great importance to prosperity.

---

<sup>4</sup> ‘Neue Bundesländer’ are the federal states of Germany which belonged to the German Democratic Republic before the German unification in the year 1990.

\*:These dots are the computed total gross value added per person in employment of a rural district or town of the federal state

Figure 3: Gross value added per person in employment in selected inland administrative rural and urban districts.

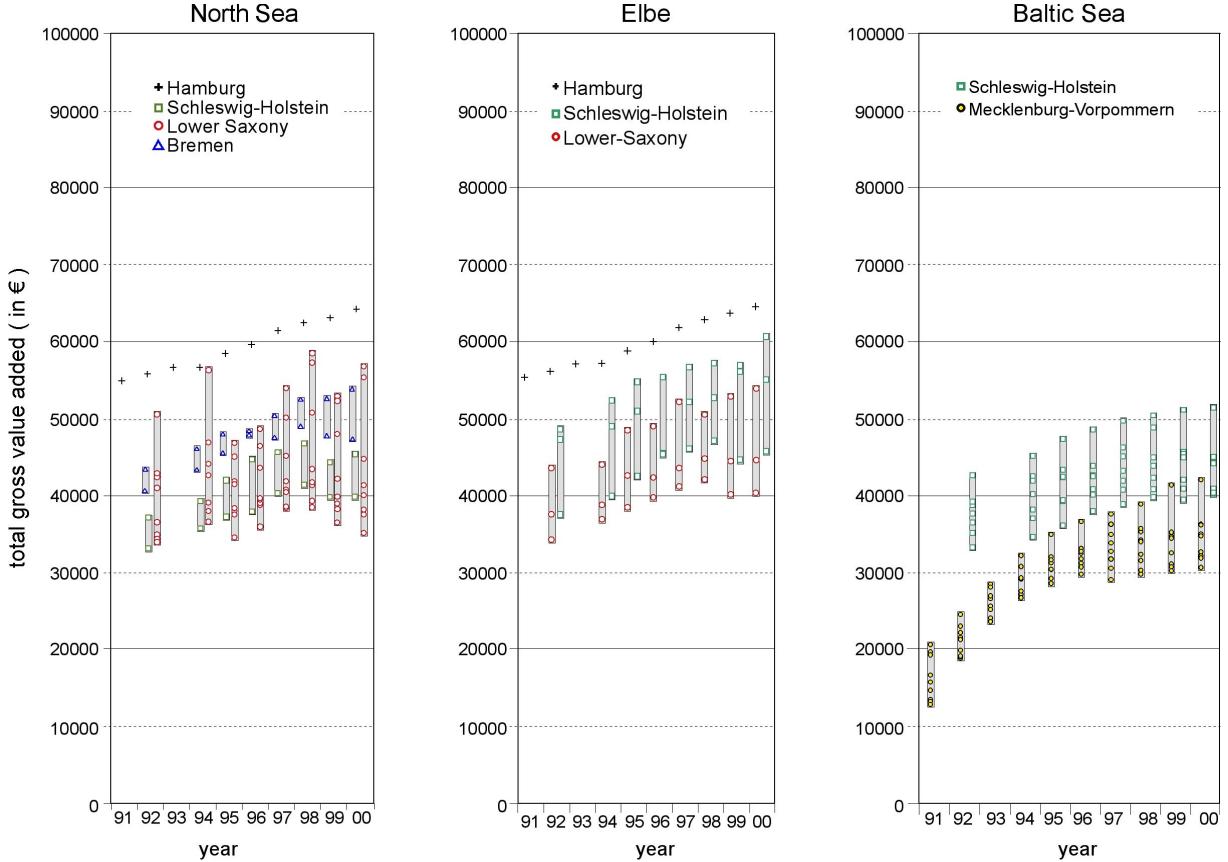

Figure 4: Gross value added per person in employment along the German coast.

Due to the gross value added per person in employment in districts at the North Sea and inland districts an advantage of location at the coast does not become apparent. The thesis that coastal regions have higher economic resources than the inland is not valid for the German North Sea (figure 4). Even in the harbour city Hamburg, in which the level of the economic indicator rose from about 55,000 € to 64,000 € in the years 1991–2000 the economic productivity was far below that in the suburbs of Munich where very productive service industries were located. This applies also to the district Ludwigshafen in Rhineland-Palatinate, a town where large chemical industries are located. There the gross value added per person rose from 57,000 € in the year 1992 to 71,000 € in 2000. Even worse is the comparison of the coastal towns Bremen and Bremerhaven with the highly productive inland towns. Over the period 1991–2000 the gross value added per person in Bremen declined from 67 % to 55 % of that generated in the Munich district. In comparison to Bremen, Hamburg fell from 87 % to 65 % of this economic indicator in the Bavarian district in those years (tables 1 and 2). The low level is perhaps caused by a higher share of less productive economic sectors as for example administration, university, location of federal armed forces, and processing industries with less added value such as shipbuilding.

Another way to assess the economic productivity of Hamburg and Bremen is to compare them to Berlin, as all three have the peculiarity of being a city state. In this comparison Hamburg has the highest gross value added per person, followed by Bremen and Berlin where about 45000 € per person in employment were generated in the year 2000.

The rear light of coastal towns along the North Sea is Wilhelmshaven. In this town the development of the total gross value in the years 1995, 1999 and 2000 is negative. In 1995 that was a result of a decrease in the service sector (table 5). The recent decline is determined by the processing industries which produced 30 % less in the year 1999 (table 11). With a gain of a gross value added of about 45000 € per person in employment in the year 2000, Wilhelmshaven gains similarity to the economic productivity of rural districts along the North Sea than to large towns (table 2). However the level of total gross value per person is comparable to that produced in urban districts (towns) in Schleswig-Holstein along the Baltic Sea (figure 4and table 3).

The most productive administrative districts of Lower Saxony along the North Sea are Emden and Wesermarsch (tables 2 and 8). The gross value added of the urban district Emden is comparable with that generated in Cologne. Emden is a town where in general a higher gross value added per person is generated than in rural districts. In the district Wesermarsch the manufacturing sector has a high productivity. The other coastal districts in Lower Saxony are as productive as the most structurally lagging, rural regions in the ‘Alte Bundesländer’.

The two coastal administrative districts belonging to Schleswig-Holstein, namely Dithmarschen and Nordfriesland, are rural areas without economic sectors generating a high gross value added. The economic structure of the districts Aurich, Wittmund, Friesland and Osterholz in Lower Saxony are comparable. In general the gross value added per person in employment in those districts is on an equivalent level to that in rural districts in the ‘Alte Bundesländer’ (figures 3 and 4).

In the centre panel of figure 4 the gross value added per person in employment along the River Elbe from the estuary to Hamburg is presented (table 2). As in the districts along the North Sea (left panel) the coastal districts, with the exception of Hamburg, do not reach the level of economic productivity of the wealthy inland districts in the ‘Alte Bundesländer’ but exceed the ‘Neue Bundesländer’. The gross value added of regions in Lower Saxony along the River Elbe is lower than along the North Sea because of the relatively economical powerful districts Emden and Wesermarsch due to their highly productive manufacturing sector (tables 2 and 8). The high level of prosperity in the district Stade is caused by a highly productive processing sector (tables 2 and 11). Additionally parts of the service sector, namely the banking and insurance branch, leasing and private services, which create high added value, are located there (table 5).

A very productive service sector is also the reason for the wealth in the two districts Steinburg and Pinneberg in Schleswig-Holstein along the Elbe. Again, as in the surrounding area of Munich, service industries with high added value tend to be located around larger cities. Steinburg and Pinneberg with a gross added value per person in employment by the service sector of about 62,000 € and 57,000 € in the year 2000 benefited from their vicinity to Hamburg (table 5). Hence the economic effectiveness is much lower in the rural district Dithmarschen (figure 4 and table 2).

Coastal districts along the Baltic Sea are shown in the left panel of figure 4. The gross value added per person in employment is significantly higher in Schleswig-Holstein than in Mecklenburg-Vorpommern (table 3). Only in the coastal town district Rostock does the level of productiveness exceed that of the rural districts Ostholtstein and Ploen in Schleswig-Holstein. In the districts Ostvorpommern and Rügen the lowest gross value added per person in employment is produced. Over the period 1991–2000 it increased from about 13,000 € to 32,000 € (table 3). This amount is even lower than in the most structurally lagging, rural regions in the ‘Neue Bundesländer’ Brandenburg and Saxony-Anhalt (table 1). In Rostock, however, the economic productivity is higher than in other inland towns of those two ‘Neue Bundesländer’ due to the higher gross added value per person in the manufacturing and service sectors (tables 4, 6, 7, 9). This factor also explains the lower level of economic effectiveness in the other coastal towns of Mecklenburg-Vorpommern, Wismar, Stralsund and Greifswald.

The economic productivity in rural districts along the Baltic Sea in Schleswig-Holstein is comparable to that in the structurally lagging inland districts of the ‘Alte Bundesländer’ with exception of Bavaria, where it is higher (figures 3 and 4). But in the town districts Kiel, Lübeck and Flensburg a gross added value per person in employment is produced which is far below the highly productive regions, for example the suburbs of Munich or the town Ludwigshafen. Not only the productivity in the service sector but also in the manufacturing sector is lower. In the year 2000 an amount of 42,000 € gross added value per person in the service sector was produced in the town Flensburg compared to 109,000 € in the suburbs of Munich (tables 4 and 6). The district Ludwigshafen which has the highest level of added value per person in the manufacturing sector, i.e. about 95,000 € in the year 2000, exceeds Kiel and Lübeck by a factor of about 2 (54,000 € are computed in Kiel and 48,000 € in Lübeck: in the year 2000) (tables 7 and 9).

Compared to the gross value added per person in employment along the North Sea and the River Elbe the districts along the Baltic Sea are overall less wealthy. This is mainly caused by districts in the ‘Neue Bundesländer’. Moreover the towns Hamburg and Bremen and the surrounding districts are by far more economically productive than coastal towns along the Baltic Sea.

In figures 5 and 6 the total gross added value in respective producer prices not adjusted to inflation in the years 1992–2000 is divided in different economic sectors

- service sector,
- manufacturing sector,
- processing sector,
- agriculture, forestry and fishery.

The bars in the figures represent the share in gross added value by the four different economic sectors. In nearly all coastal regions, along the North and Baltic Sea and the River Elbe, the gross value added is mainly produced by the service sector. This agrees with the selected inland districts of Germany (tables 4–6). The second most important sector is the manufacturing industry (tables 7–9). Agriculture, forestry and fishery produce less than 10 % of the value added although most of the coastal districts are rural regions (tables 13–15). As expected they are of nearly no economic importance in town districts located at the North Sea or at the Baltic Sea (figures 5 and 6).

Along the North Sea two districts differ from the dominant economic structure. In the town Emden and the rural district Wesermarsch the manufacturing sector is about twice as important than on average. Over the period 1991–2000 the share in gross added value in the manufacturing sector ranged between 51–61 % in Emden and between 38–48 % in Wesermarsch, mainly as a result of the automobile industry (figure 5). The gross added value per person of about 74,000 € in Emden and 68,000 € in Wesermarsch in the year 2000 indicates the high productiveness of this sector (table 8).

In the districts along the River Elbe from the estuary to Hamburg the city and the surrounding districts generate a higher percentage of the value added in the service sector than other districts (figure 5 and table 5). Additionally the sector is more productive in urban areas. In the year 2000 64,000 € were accomplished per person in Hamburg, 57,000 € in Pinneberg but only 43,000 € in Dithmarschen. In two districts, Hamburg and Stade, the processing sector has the highest productivity of the four economic sectors presented in the tables. In Dithmarschen the manufacturing sector dominates (table 8).

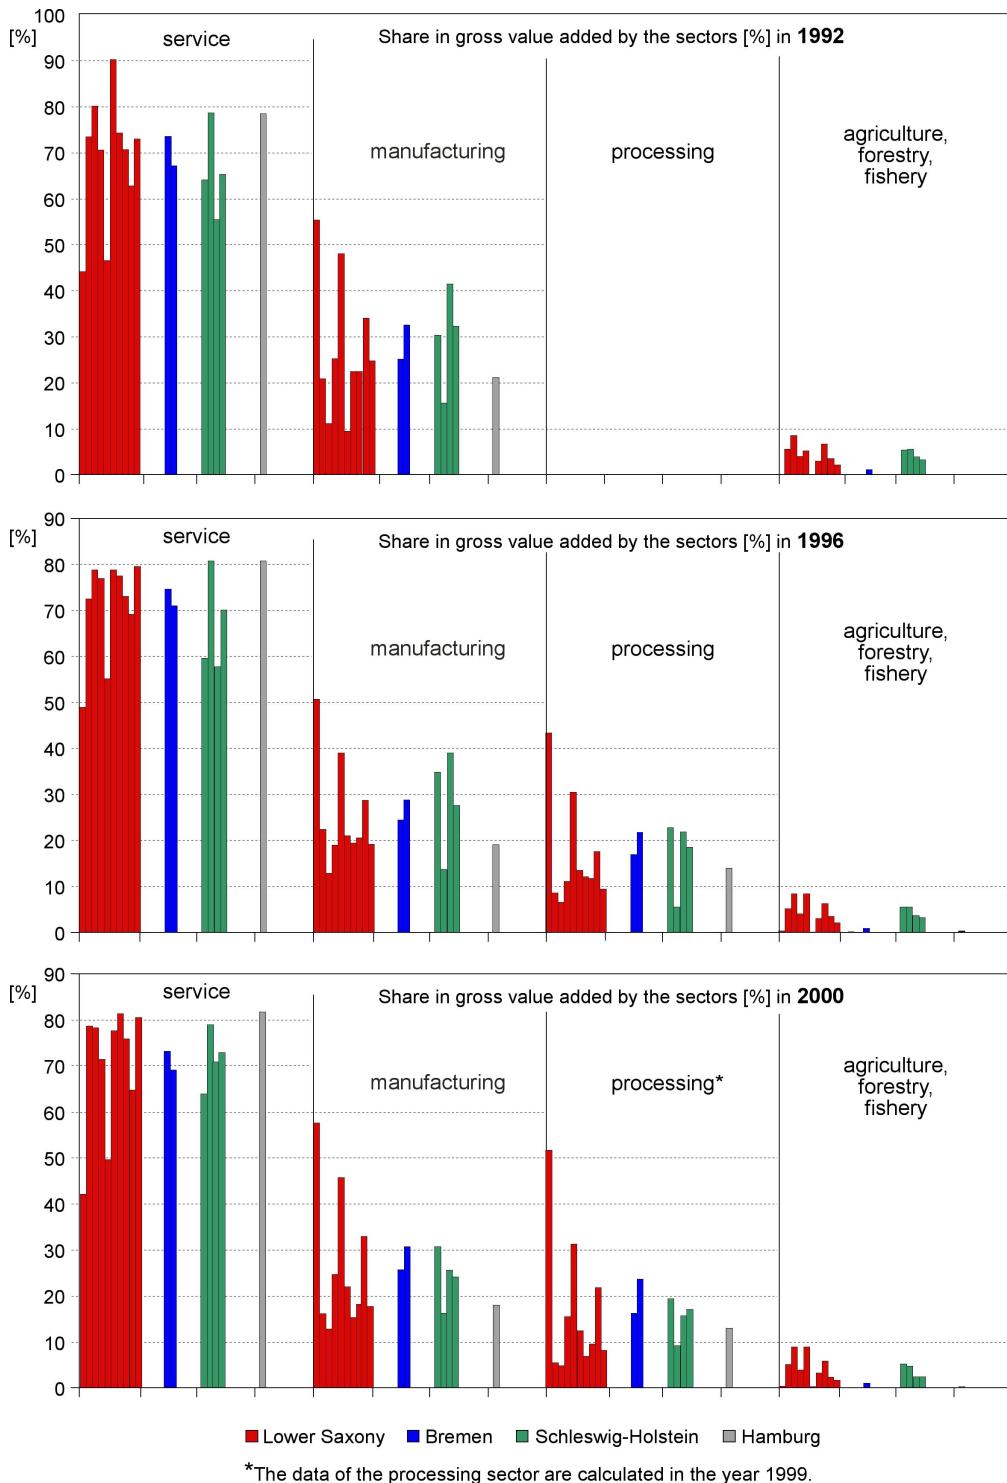

Figure 5: Share of different economic sectors in total gross value added in administrative rural and urban districts in the four federal states along the North Sea in the years 1992–2000.

Along the Baltic Sea the service sector is more productive in Schleswig-Holstein than in Mecklenburg-Vorpommern, except to the town Rostock (table 6). Although in all Baltic Sea districts the dominant share of gross value added is generated in the service sector, the sector with the highest

productiveness varies regionally. In Flensburg, Rendsburg-Eckernfoerde and Kiel the highest gross added value per person is produced in the processing sector. In Wismar and Rostock 38,000 € and 48,000 € were generated in the manufacturing sector in the year 2000 compared to 36,000 € and 41,000 € in the service sector (tables 6, 9 and 12).

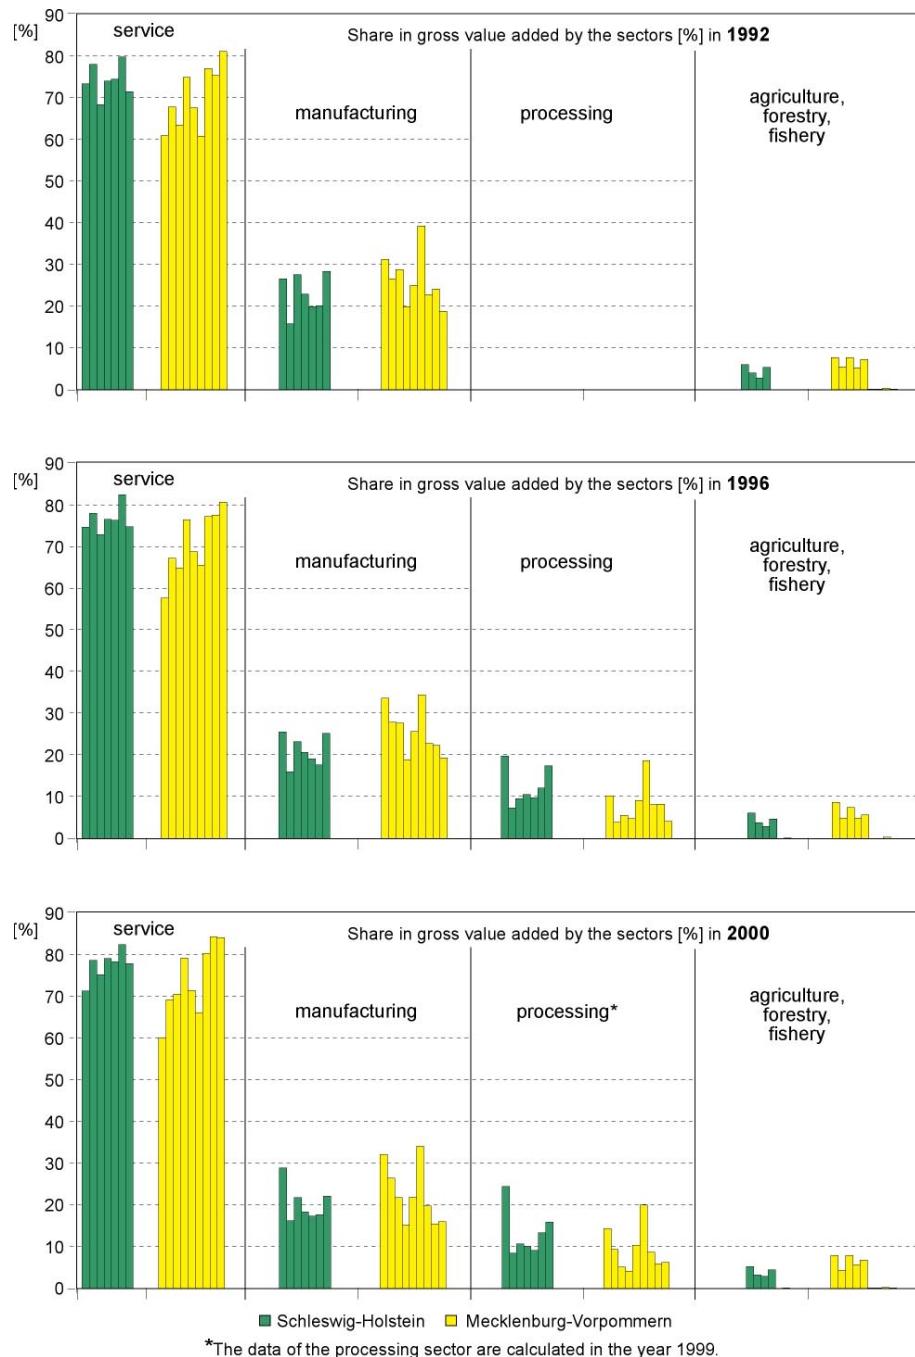

Figure 6: Share of different economic sectors in total gross value added in administrative rural and urban districts in the two federal states along the Baltic Sea in the years 1992–2000.

In nearly all rural and town districts in Schleswig-Holstein along the North Sea and the Baltic Sea the sector agriculture, forestry and fishery is the least productive (tables 14 and 15). However, in the rural districts Aurich, Wittmund and Friesland in Lower Saxony the gross value added per person in the agricultural sector exceeds that in one or more of the other three economic sectors. Also in the three rural districts Nordvorpommern, Ruegen and Ostvorpommern in Mecklenburg-Vorpommern the highest gross added value per person in employment is generated in agriculture, forestry and fishery, although the share in total gross value is still low. However this indicates the low productivity of the service, manufacturing and processing sectors in this area.

#### 4 CONCLUSIONS

The total gross value added in towns is far beyond that in rural areas. This difference is much larger than regional differences between the North Sea and the Baltic Sea and the districts along the River Elbe which are considered in this paper. However the gross added value per person in employment is more meaningful as the amount of workers, self-employed persons and entrepreneurs differ a lot between the areas discussed. Comparing the regions on the basis of this indicator shows that Hamburg has the highest economic productivity of all German coastal districts. Again the town districts are superior to the rural areas. This is mainly caused by a higher productivity in the service and manufacturing sectors in towns and their suburbs. Overall the coastal cities do not reach the level of very wealthy inland districts as for example the suburbs of Munich or the town Ludwigshafen.

Coastal rural areas not influenced by the economic activity of larger towns have comparable levels of gross added value to that of structurally lagging inland districts. As expected a different level of economic productivity still exists in the ‘Alte Bundesländer’ compared to the ‘Neue Bundesländer’. Therefore the gross added value per person in coastal districts of Mecklenburg-Vorpommern is comparable to that generated in inland districts of Brandenburg or Saxony-Anhalt and is significantly lower than in districts along the North Sea or the lower part of the River Elbe.

In the whole area discussed in this report the main share of gross added value is generated in the service sector. Additionally this sector is the highest productive industry in most of the administrative districts and towns. However in some areas, especially in towns along the German coast, a higher gross added value per person in employment is generated in the manufacturing sector or in its sub-category the processing sector. Agriculture, forestry and fishery have a minor economic relevance, even in rural areas less than 10 % of the gross value added is produced by these sectors.
